Responsive Design Testing Report

Test scope

The assignment requires each standalone HTML5 prototype to be considered at **375px mobile, 768px tablet, and 1440px desktop**. The final source and QA checklist were reviewed against those targets.

All test was done in both Chrome (mobile,tablet and desktop) and Microsoft Edge

The prototypes use different responsive strategies because their product models are different:

- **Code Flow:** mobile-first and progressively expands.
- **Code Flow Pro:** desktop-first professional workspace with adaptive panels.
- **Code Flow Signal:** desktop/tablet-first exploratory canvas with mobile fallbacks.

The report describes the intended layout behavior and the final QA status recorded in `qa_test.md`.

Prototype 1 --- Code Flow

Width	Responsive behavior
375px	Primary experience
768px	Tablet experience
1440px	desktop wider centered layout

P1 responsive principle

P1 uses responsiveness to preserve simplicity, not to add production complexity.

375px --- Mobile

Expected behavior: The mobile-first guided flow remains the primary experience. Content is kept focused, with a contextual header and bottom action area rather than a large desktop workspace.

Result: Pass based on the latest bundled implementation

768px --- Tablet

Expected behavior: The guided workflow gains additional horizontal breathing room through the responsive utility/layout rules while preserving the same simple step-by-step interaction model.

Result: Pass based on the latest bundled implementation

1440px --- Desktop

Expected behavior: The experience remains intentionally constrained and readable rather than stretching into an unnecessary professional editor. The product philosophy stays "simple creation," not "desktop NLE."

Result: Pass based on the latest bundled implementation

Key breakpoint strategy:
The actual breakpoint is at 640px, 1024px for standard

Small Tablet / Large Phone (640px): Standard starting point (`sm` in Tailwind CSS) for landscape phones and compact tablets

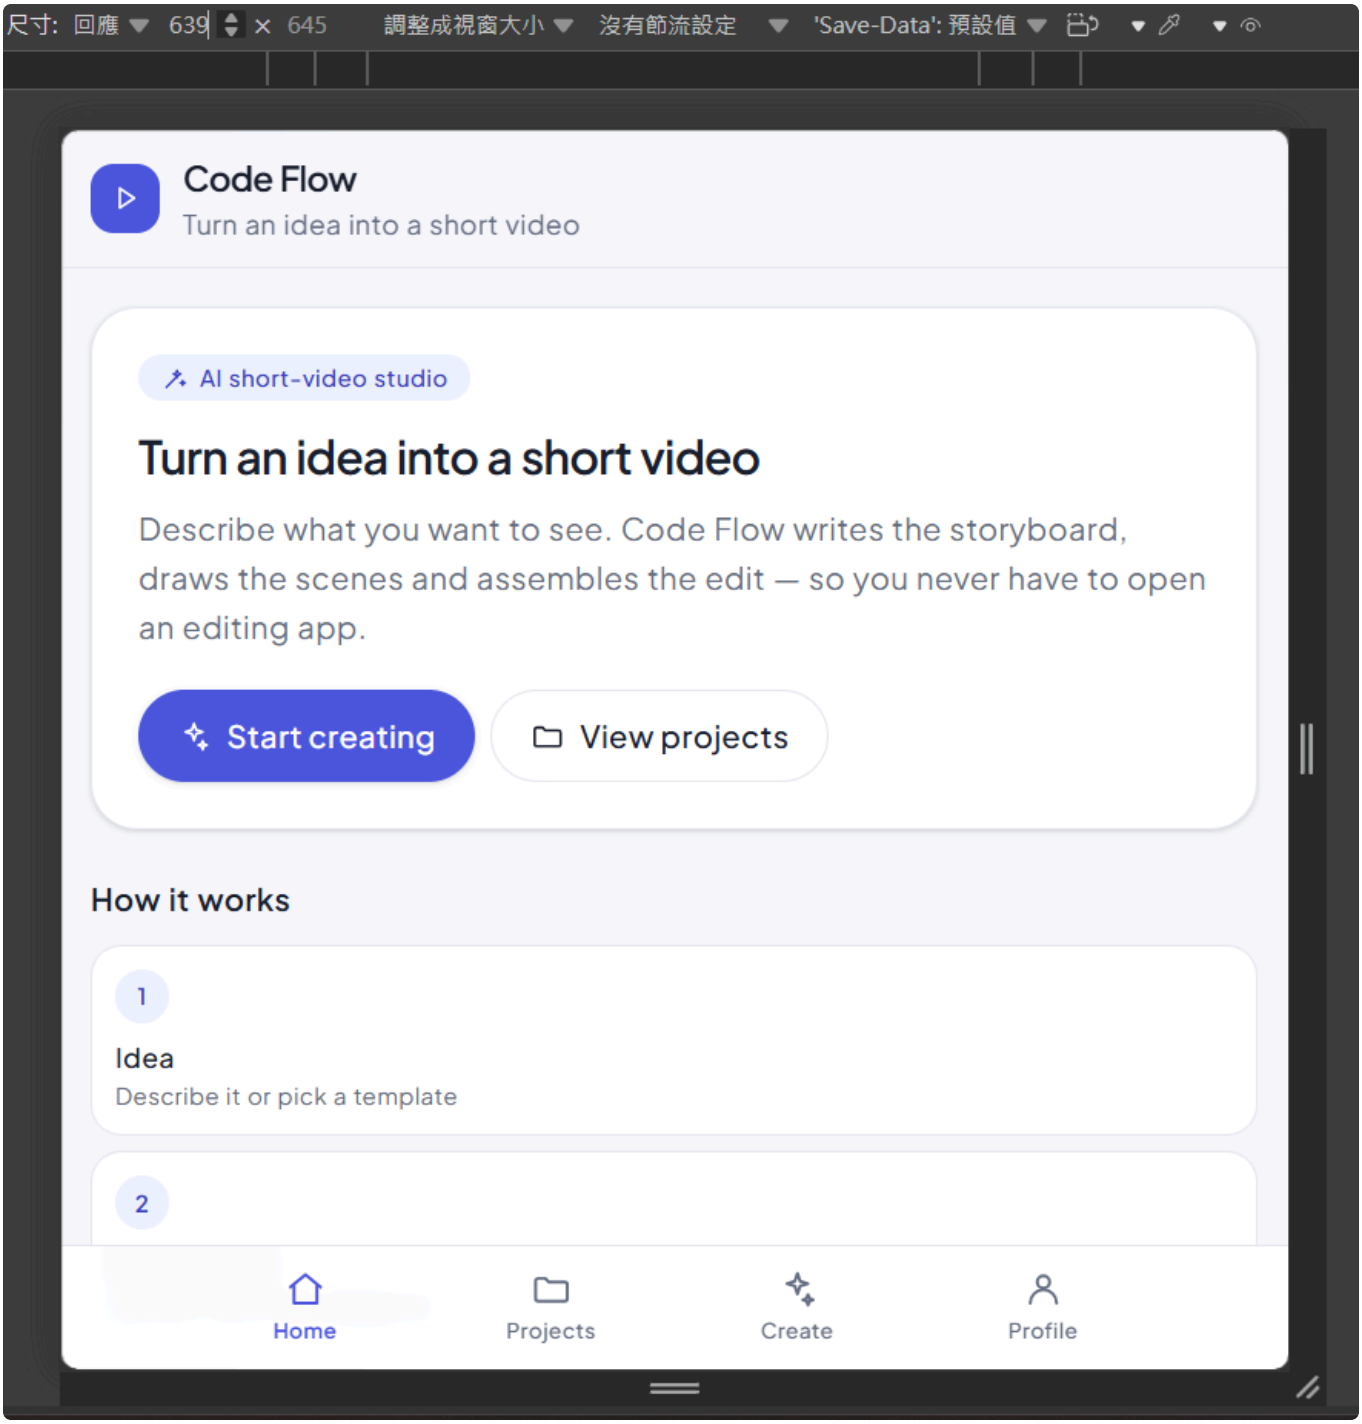

Laptop / Small Desktop (1024px): Standard width (`lg` in Tailwind CSS) for landscape tablets, netbooks, and smaller laptops

Design trade-off: P1 deliberately does not use the extra desktop width to expose every production control. This preserves its casual-creator identity.

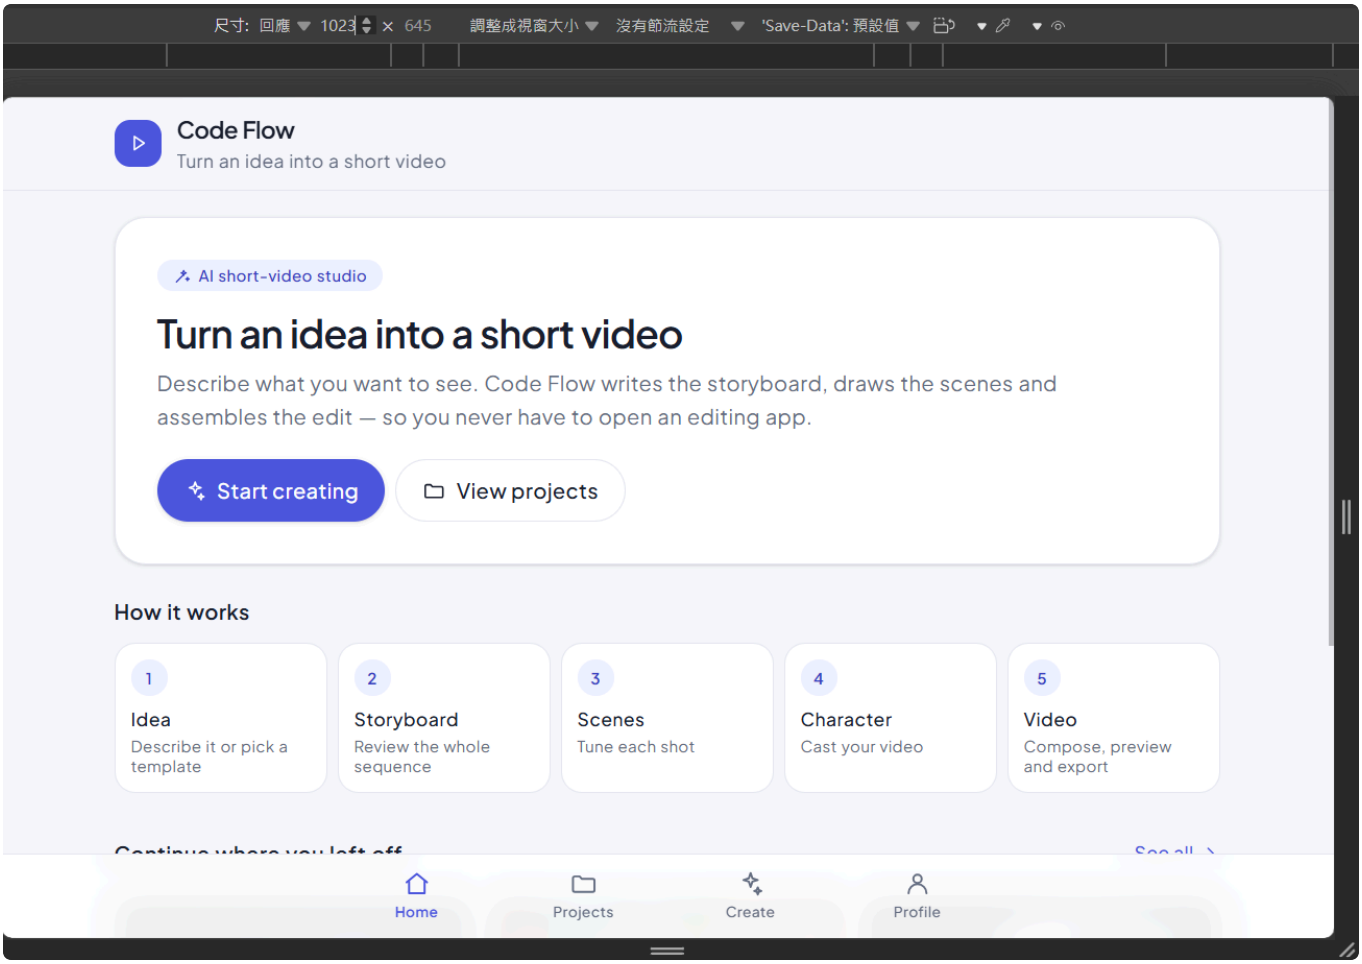

Code flow is focusing on mobile experience first and we adapt upward to tablet and desktop

All screenshot below is captured at standardized testing environment (Devtools) and will look significantly better in real time

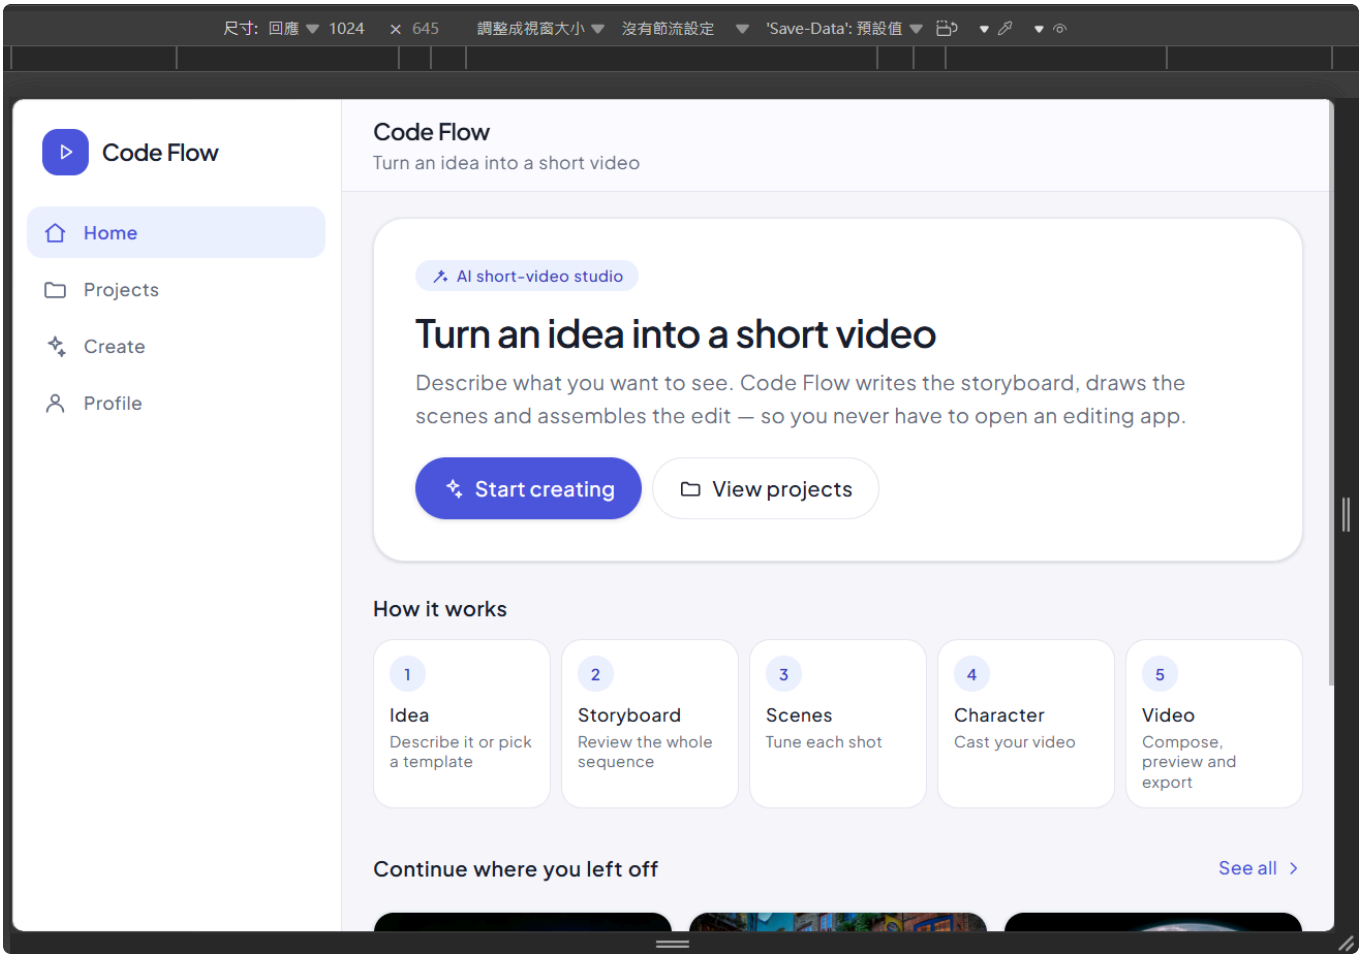

Mobile screenshot (< 640px)

Tablet screenshot (>= 640px and < 1024px)

Desktop screenshot (>= 1024px)

Prototype 2 --- Code Flow Pro

Width	Responsive behavior	
375px	mobile/adaptive	
768px	Tablet/adaptive	
1440px	Full professional	

P2 responsive principle

P2 does not simply shrink the desktop editor. It intentionally changes the editing model:

Mobile → lighter editing / adaptive panels → Tablet → partial professional workspace → Desktop → full professional workspace.

This is the key responsive design decision for the professional prototype.

375px --- Mobile

Expected behavior: - single-column/light editing experience - project navigation is not permanently consuming desktop-style width - Inspector is handled as an adaptive/slide-over panel rather than forcing a three-column desktop layout - stage content is protected from page-level horizontal overflow

Result: Pass based on the latest implementation

768px --- Tablet

Expected behavior: - project/navigation context can become docked - Inspector remains adaptive rather than forcing the full desktop workspace - the editor remains usable without requiring the 1440px desktop arrangement

Result: Pass based on the latest implementation

1440px --- Desktop

Expected behavior: - full professional workspace is enabled - navigation, stage, and Inspector can occupy their intended desktop positions - the production/timeline experience has enough space to show its professional controls - stage/grid sizing uses

Result: Result: Pass based on the latest implementation

Key breakpoint strategy:
The actual breakpoint is at 768px, 1024px for standard

Tablet (768px): Standard width for portrait iPads and mid-sized tablets

Standard Desktop (1280px - 1440px): Scales out content for full desktop monitors

Code flow pro is desktop first and we adapt downward to tablet and mobile

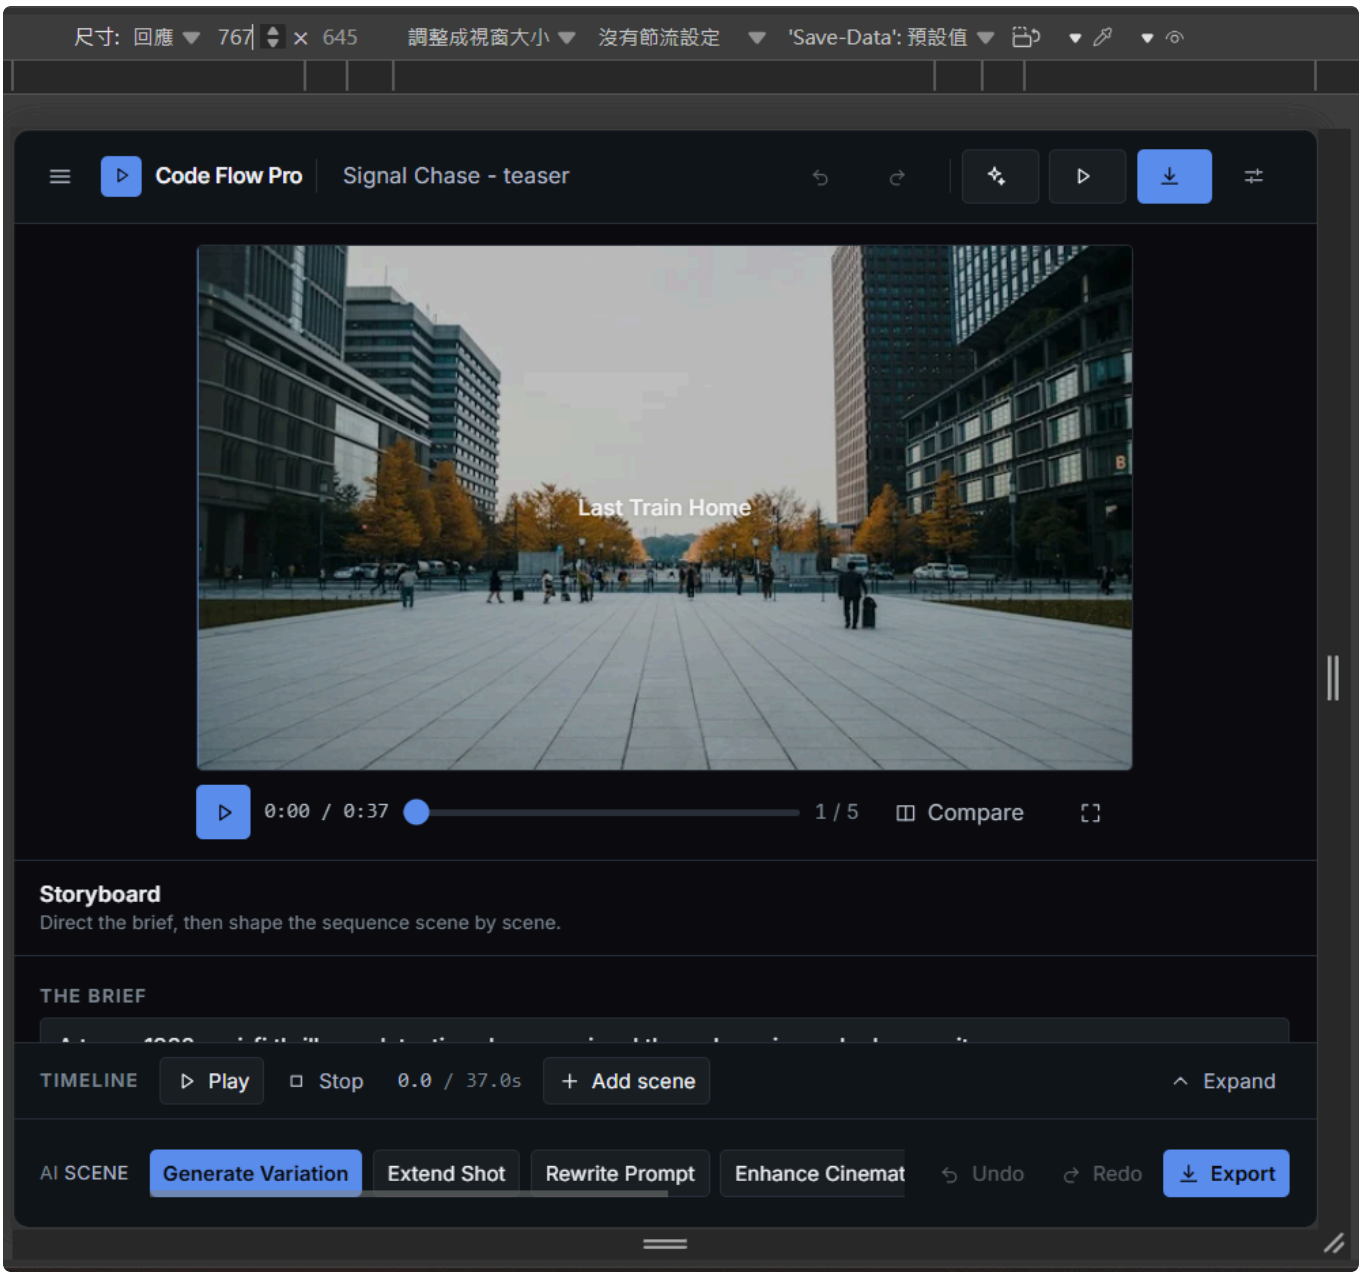

Breakpoints: the implementation uses **768px** as the adaptive/docked-navigation threshold and **1440px** as the full three-column professional workspace threshold.

At ≥1440px, the layout uses the full production workspace. At 768--1439px, panels can collapse/adapt. Below 768px, the design avoids forcing the desktop editor onto mobile.

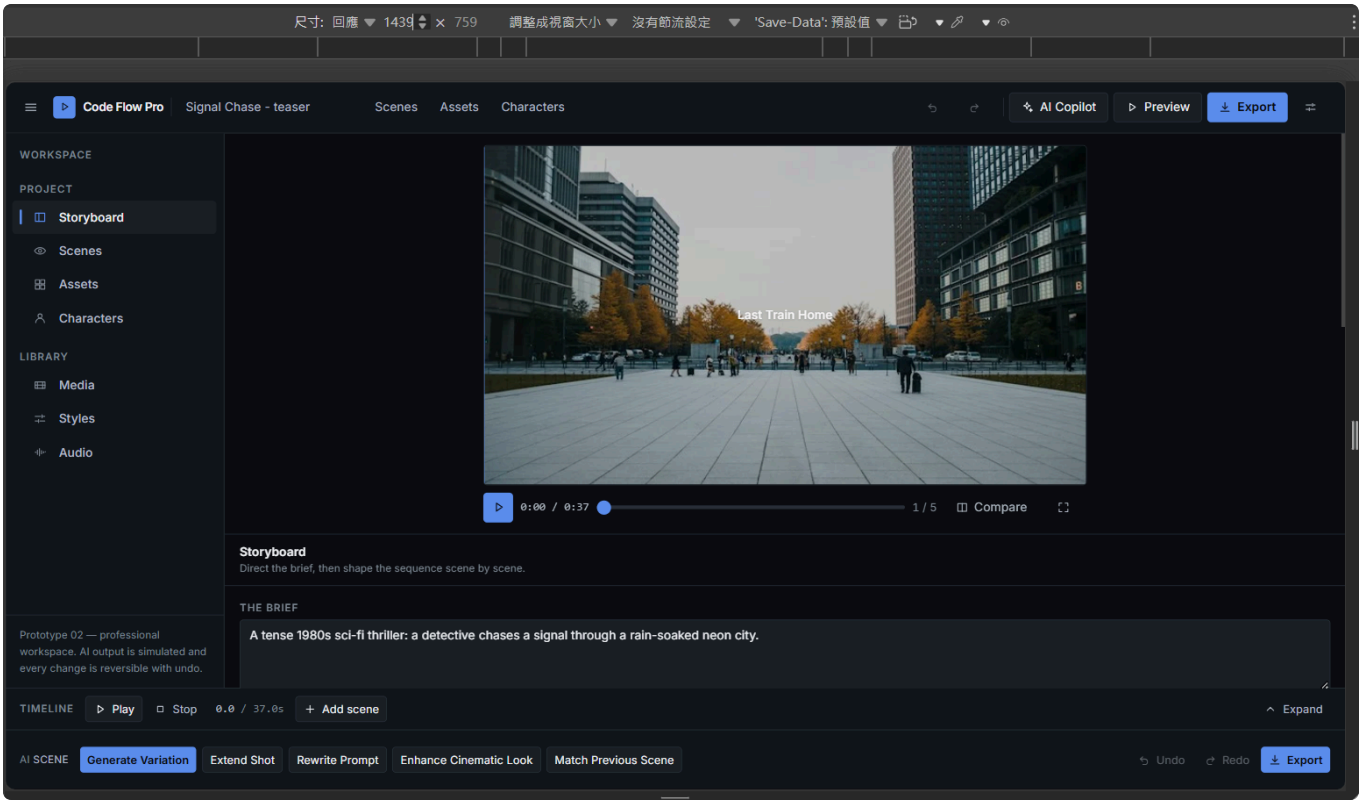

Design trade-off: P2 prioritizes professional control and information density on desktop. Smaller screens intentionally receive a lighter editing experience rather than pretending that a full NLE-style workspace can remain equally usable everywhere.

All screenshot below is captured at standardized testing environment (Devtools) and will look significantly better in real time

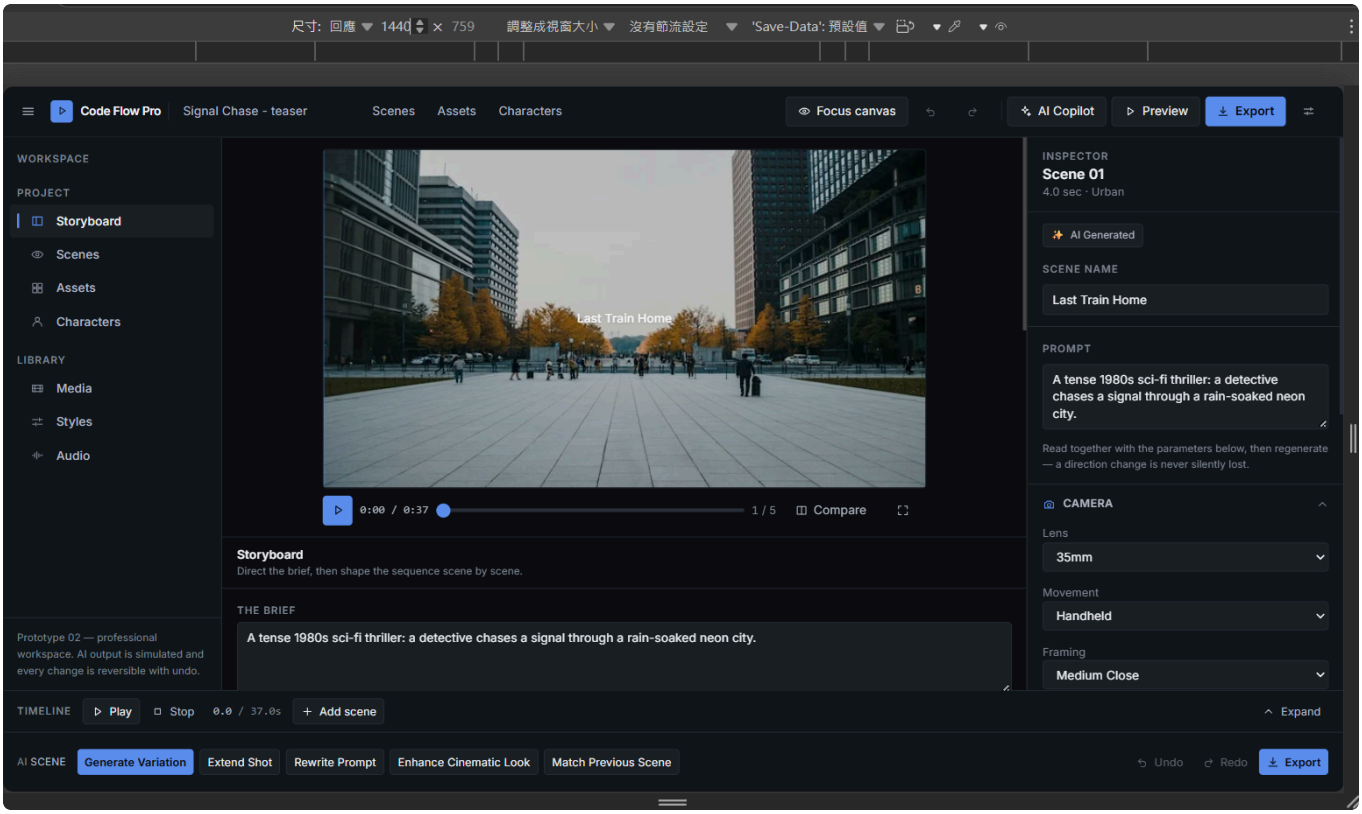

Mobile screenshot (< 768px)

Tablet screenshot (>= 768px and < 1440px)

Desktop screenshot (> 1440px)

Prototype 3 --- Creative Signal

Width	Responsive behavior
375px	mobile/adaptive
768px	Suitable important exploratory
1440px	Full exploratory

P3 responsive principle

P3 is intentionally tablet/desktop-first because its core interaction is exploratory and spatial. Mobile preserves the concept rather than pretending that node exploration has the same richness on a narrow screen.

375px --- Mobile

Expected behavior: - compact single-column/fallback presentation - terminal-style navigation remains contained and can scroll within its own area where necessary - the signal-first workflow remains understandable - text input remains available alongside the simulated voice interaction

Result: Pass based on the latest bundled implementation

768px --- Tablet

Expected behavior: - the Creative Universe receives more room - navigation and exploratory surfaces become more spacious - the node-based exploration model becomes more comfortable without requiring the full desktop width

Result: Pass based on the latest bundled implementation

1440px --- Desktop

Expected behavior: - full exploratory workspace - larger Creative Universe/node area - complete terminal/navigation treatment - enough space for synthesis, branching, and cinematic exploration

Result: Pass based on the latest bundled implementation

Key breakpoint strategy:
The actual breakpoint is at 768px

Tablet (768px): Standard width for portrait iPads and mid-sized tablets

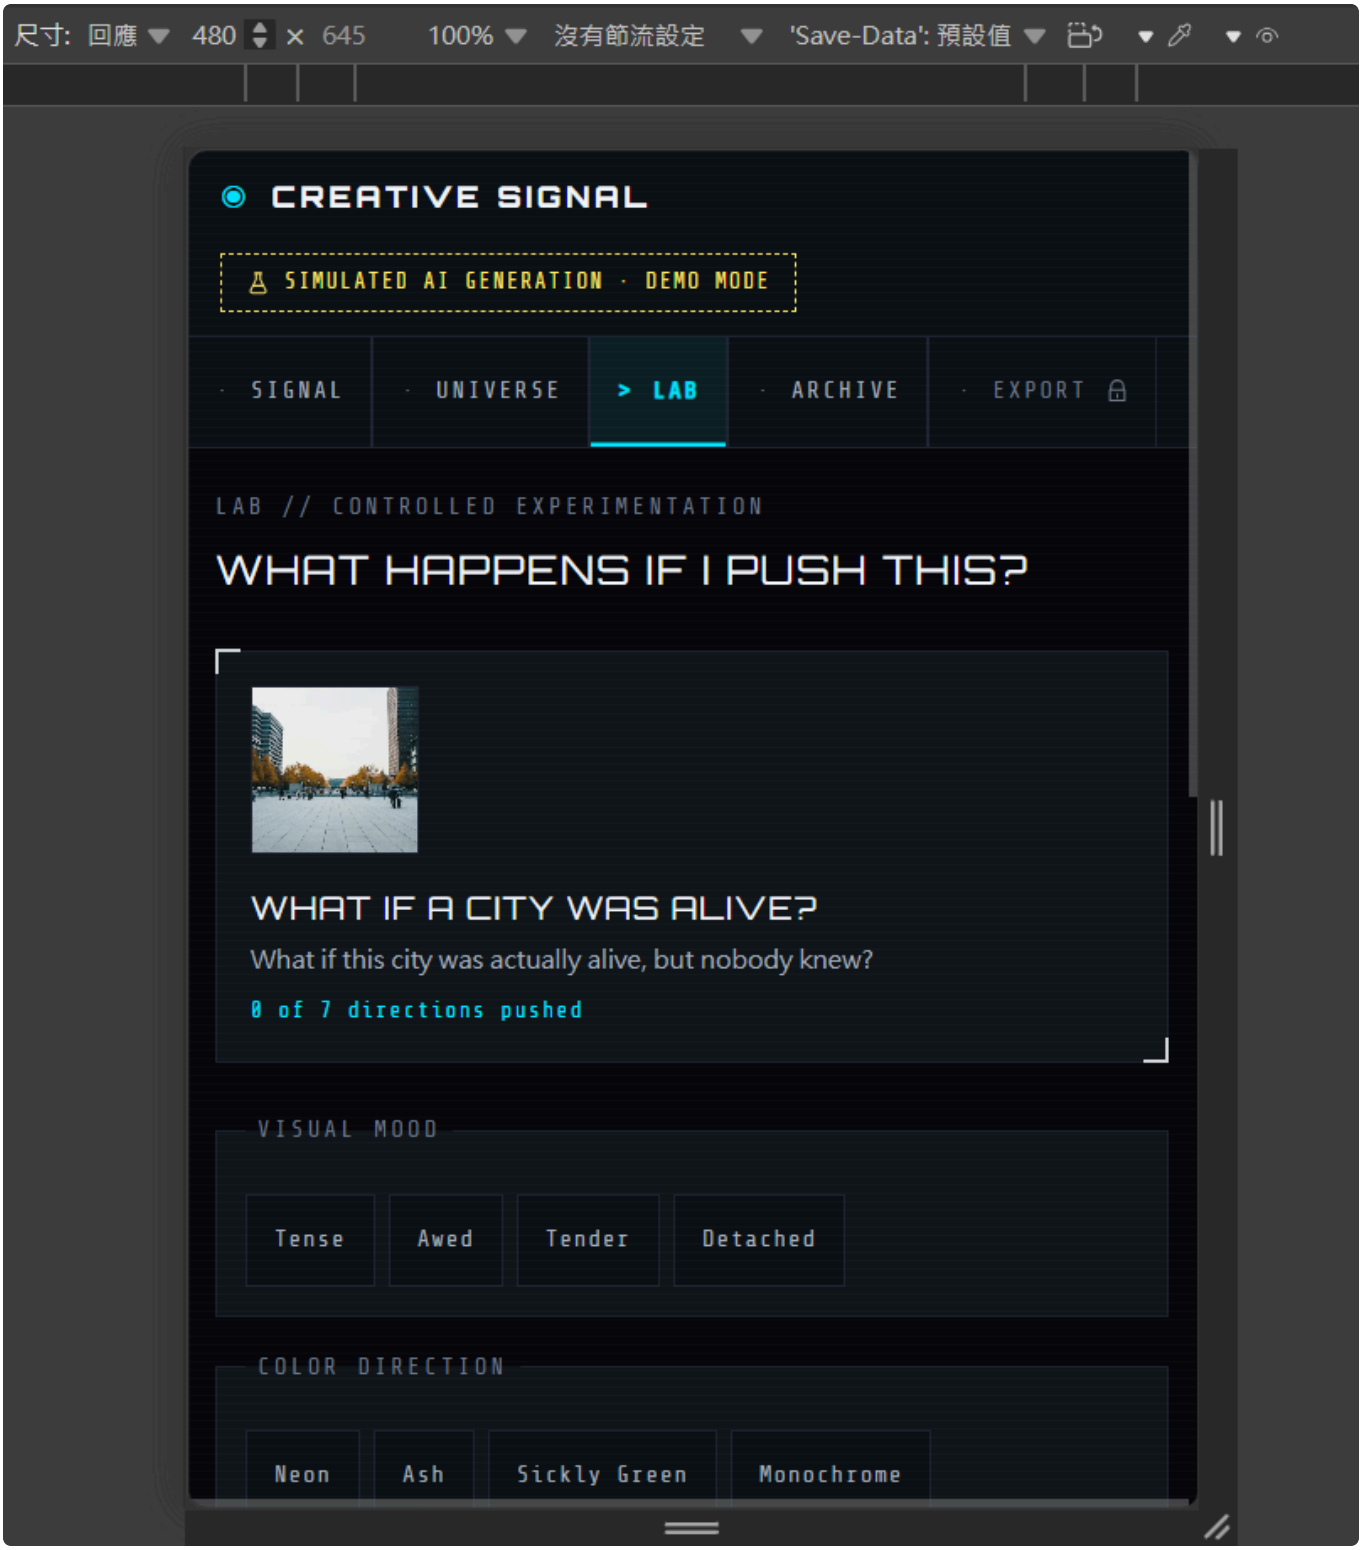

Standard Desktop (1280px - 1440px): Scales out content for full desktop monitors

Breakpoints: the main navigation adapts at **768px**; several views use additional **480px** or similar narrow-screen adjustments for padding, typography, and content wrapping. The terminal navigation uses horizontal scrolling rather than allowing its contents to create page-level overflow.

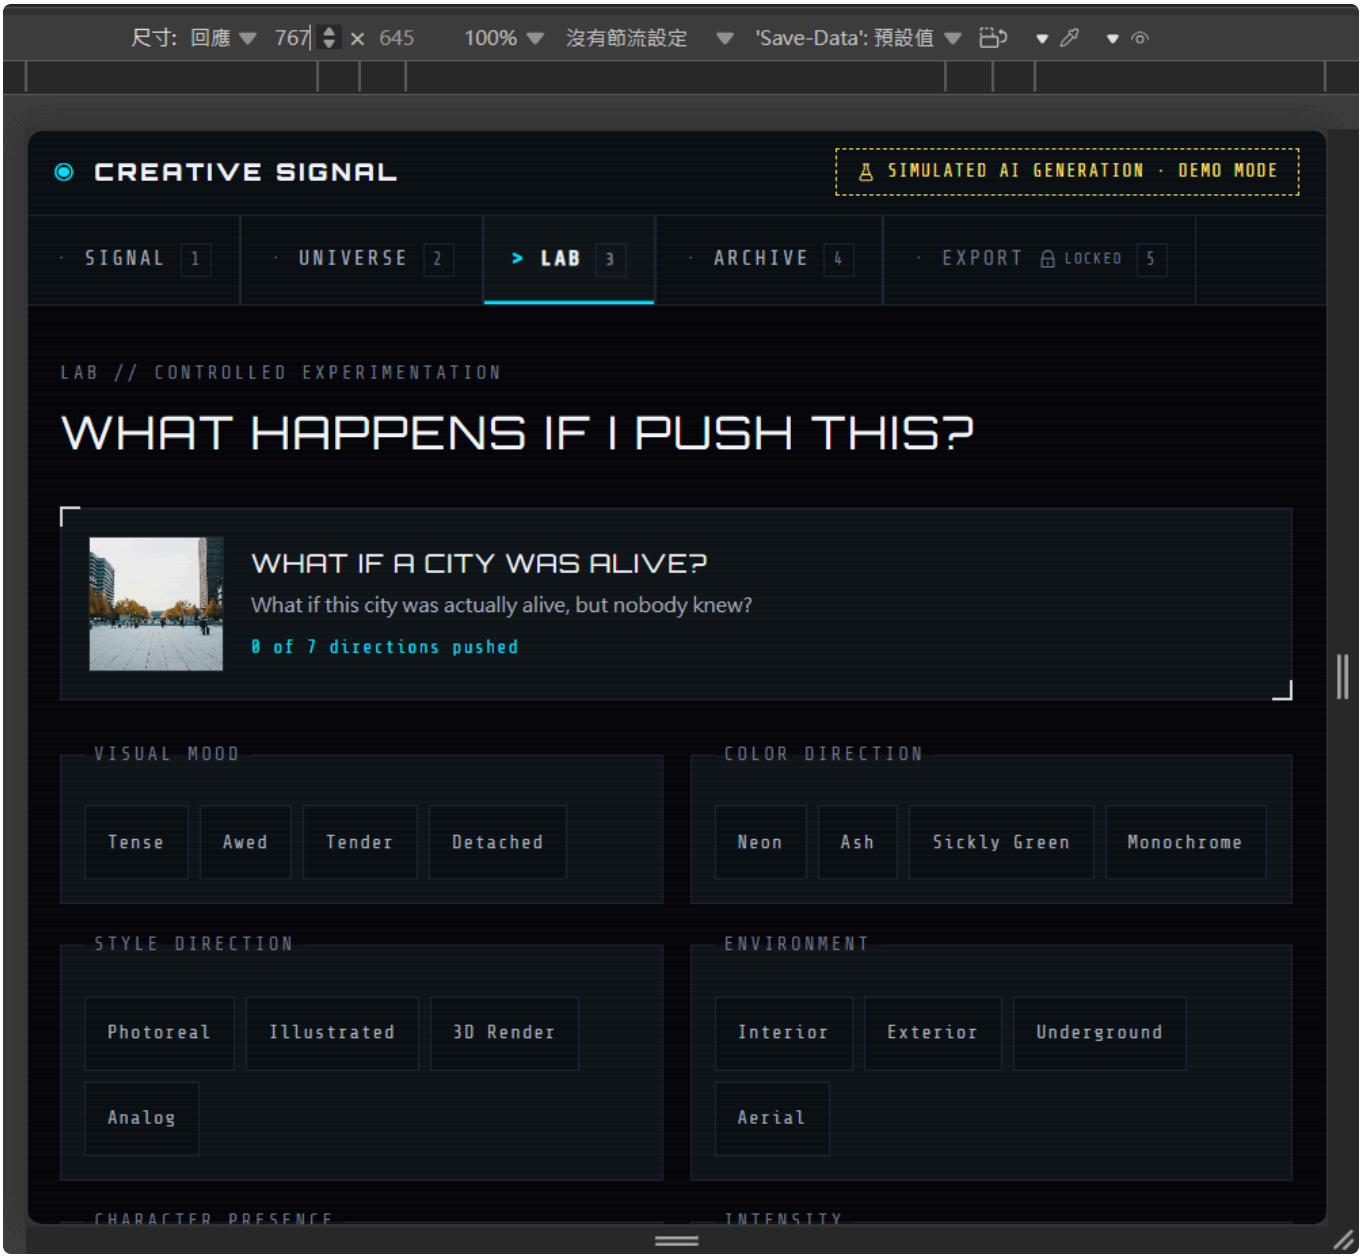

Because of design choice , both desktop and tablets experience remain highly similar with small difference with less navigation treatment and less node area

Design trade-off: P3 is intentionally desktop/tablet-first because node exploration, combination, and branching benefit from space. Mobile retains the core workflow but is not intended to be the richest P3 experience.

Cross-prototype findings

Responsive strengths

1. The three prototypes do not use one generic responsive solution; each adapts according to its product philosophy.
2. P1 preserves simplicity at every width.
3. P2 changes interaction density at smaller widths rather than simply shrinking the desktop editor.
4. P3 preserves the exploratory interaction model while allowing terminal navigation to scroll within its own container.
5. Touch/accessibility alternatives are considered alongside visual responsiveness.

Accessibility / responsive considerations

- The prototypes consider responsive behavior together with accessibility:
- semantic/labelled controls
- keyboard-oriented interaction paths
- visible focus considerations
- reduced-motion support
- alternatives to gesture-only interactions

- compact mobile layouts rather than merely scaling desktop UI

Known limitations / honest trade-offs

- P1 is intentionally less information-dense than a professional editor.
- P2's richest experience is desktop-first; mobile is a reduced production experience.
- P3's Creative Universe benefits substantially from tablet/desktop space.
